

1. Focus on experimentation over long narrative

- The project should primarily be experimental and comparative, not theoretical.
- Try different preprocessing steps and model variants, and clearly report what works best.
- The emphasis should be on comparison, not just one final model.

2. Results presentation

- Present results clearly in tables and discuss them in the text.
- Use precision, recall, and F1-score (macro vs. micro should be justified depending on class balance).
- For multiple runs:
 - Repeat experiments with different stratified splits
 - Report mean and standard deviation
 - Discuss stability of results
- In tables:
 - Highlight the best result per metric (e.g., best precision/recall/F1 in bold)
 - Use tables instead of overly long text descriptions when possible
- For figures:
 - If figures are small, increase font size for readability
 - If using bar charts, consider also showing the exact values as annotations

3. Writing and structure

- Keep the report concise and focused.
- Suggested structure:
 - Brief introduction (no long background sections)
 - Strong emphasis on experiments and results
- Avoid unnecessary content such as:
 - CCS concepts
 - Overly detailed or abstract introductions
 - References to Python scripts in the main text
- The main text should be around 4 pages (references and appendix excluded).

4. Tables vs figures vs text

- Use tables when precision is important or when multiple results need to be compared compactly.
- Use figures when trends or comparisons benefit from visualization.
- Avoid duplicating the same information in both text and tables.

5. Appendix and space management

- References and appendix do not count toward page limits.
- Appendix should be used only for additional material, not essential content.
- Avoid overusing the appendix, core insights should remain in the main text.
- Remove redundant elements (e.g., keyword sections) to save space.
